Determination of the transfection efficiency of mouse embryonic fibroblasts (MEFs)

Marc Germain, Department of Medicine, University of British Columbia and Vancouver Coastal Health Research Institute, Jack Bell Research Centre, 2660 Oak St. Vancouver, BC, Canada, V6H 3Z6

Introduction:

MCL-1 is an anti-apoptotic BCL-2 homologue that regulates cytochrome c release from mitochondria. In order to determine the role of the N-terminus of MCL-1 in the anti-apoptotic function of MCL-1, we analyzed the effect of various truncation mutants in MCL-1 null MEFs. As these MEFs proved rather difficult to transfect, we tested several transfections reagents.

Materials and methods:

Wild type and MCL-1 knockout MEFs were cultured in DMEM supplemented with 10% heat-inactivated foetal bovine serum, 20 mM L-glutamine, 100 mM β-mercaptoethanol and 0.1 mM non-essential amino acids, as described (1)

Experimental:

Transfections reagents were used according to the manufacturers’ instructions.

Results and discussion:

MEFs were first transfected with GFP using Lipofectamine LTX, Lipofectamine 2000, Lipofectine, Effectene or Metafectene Pro and analyzed by fluorescence microscopy. While a few green cells were observed with effectene, no transfected cells were observed when using Lipofectamine-based reagents. On the other hand, between 30-50% of the cells transfected using Metafectene Pro were positive for GFP signal.

Conclusion:

Metafectene Pro was thus used for all subsequent experiments using MEFs (1)
